1. Introduction

A knock sensor allows the engine to run with the ignition timing as far advanced as possible. The computer will continue to advance the timing until the knock sensor detects pinging. At that point the computer retards the ignition timing just enough for stopping the pinging.

The knock sensor responds to the spark knock caused by pre-detonation of the air/fuel mixture. As the flame moves to the front out of the spark plug ignition point, pressure waves in the chamber crash into the piston or cylinder walls resulting in a sound known as a knock or ping. This is caused by using a fuel with a low octane rating, overheating, or over advanced timing. It can sometimes be caused by hot carbon deposits on the piston or cylinder head that raise compression. A knock sensor is comprised of piezoelectric materials; crystals that when impacted, generate a voltage (same idea as a BBQ ignitor). This voltage is monitored by the computer, and when an irregularity is detected, the computer corrects timing in variable valve timing engines, or triggers Diagnostic Trouble Code in older vehicles [1-3].

• The use of a fuel with high octane rating, which increases the combustion temperature of the fuel and reduces the proclivity to detonate;
• enriching the air-fuel ratio which alters the chemical reactions during combustion, reduces the combustion temperature and increases the margin above detonation;
• reducing peak cylinder pressure by decreasing the engine revolutions (e.g., shifting to a higher gear, there is also evidence that knock occurs more easily at high rpm than low regardless of other factors);
• decreasing the manifold pressure by reducing the throttle opening, boost pressure or
• reducing the load on the engine.

At detonation combustion occurs to rapid changes in pressure (Figure 1). These fast pressure changes; generated by sound waves, which are in modern automobiles captured by the knock sensor [4].

2. Engine knocking

Detonation can be prevented by any or all of the following techniques:

3. Adaptive knock control

At dynamic engine transients, mismatches of the ignition angle occur resulting in increased knock occurrence rates. The response time of knock control can be reduced by a feed-forward control angle \( \alpha_n \) stored in an adaptive ignition angle map. Contrary to lambda control, a successful global error model has not yet been found. The values of the ignition angle map must
The factor \( k \) determines how fast the learning process is [5]. The illustration of knock control with feed-forward adaptive ignition angle map is shown in Figure 2.

The usual actuation is a retardation of the ignition angle, shifting the energy conversion process backwards and thus reducing peak pressures and temperatures. An alternative input may be to lower the boost pressure of a turbo charger. The knock control ignition angle is calculated at discrete combustion cycles \( n \) as

\[
\alpha_k(n) = \alpha_e(n) + \Delta \alpha_k(n) + \alpha_l(n)
\]

(1)

where \( \alpha_e \) is the effective ignition angle, \( \alpha_i \) is the open loop ignition angle from fixed map, \( \alpha_k \) is the knock control ignition angle, and \( \alpha_l \) is the learned ignition angle from adaptive map.

The average knock control ignition angle \( \alpha_k(n) \) is the basis to teach the adaptive ignition angle map \( \alpha_e(n) \) into the direction of retarding. A fixed advance angle \( \alpha_i \) is superimposed to the teaching process providing a forgetting function of the thought angles. The learned ignition angle is

\[
\alpha_l(n) = (1 - k)\alpha_l(n - 1) + k(\alpha_i(n - 1) + \alpha_e(n - 1))
\]

(2)

The factor \( k \) determines how fast the learning process is [5]. The illustration of knock control with feed-forward adaptive ignition angle map is shown in Figure 2.

The usual actuation is a retardation of the ignition angle, shifting the energy conversion process backwards and thus reducing peak pressures and temperatures. An alternative input may be to lower the boost pressure of a turbo charger. The knock control ignition angle is calculated at discrete combustion cycles \( n \) as

\[
\alpha_e(n) = \alpha_e(n - 1) + \Delta \alpha_e(n) - \beta \cdot E_y(n)
\]

(3)

where \( \Delta \alpha_e(n) \) is a permanent ignition angle advance, and \( \beta E_y(n) \) the ignition angle retard at knocking. A typical control cycle is shown in Figure 3. The knock control ignition angle \( \alpha_e(n) \) is added to the ignition angle obtained from the ignition map.

**Figure 3** Control of knock occurrence rate by ignition angle shifting [5]
A simple but effective test knock sensor is shown in Figure 5. The sensor is attached to a metal cylindrical body. The plastic tube is adjusted so as to allow for the impact of the metal balls of different heights $h$.

Impact of ball on a metallic material with a height of 1.8 cm and a diameter of 3.4 cm generates sound waves. These waves are captured by a knock sensor. The output voltage signal, which is shown in Figure 6, corresponds with Bessel function.

Using a measuring apparatus consisting of an oscilloscope, metal impact surface, plastic tube with adjustable height and metal ball, we tested the response the knock sensor from Bosch which was used in VW Golf. The response was stored in oscilloscope and then the values of voltage were shown in Figure 6.

The principally schematic of sound waves spreading in metal environment created by ball impact on surface of metal material is shown in Figure 7. The knock sensor is placed on the bottom of the metal plate. In the middle of the plate is screw which is tighten to rated torque. This arrangement provides the best possible transfer of mechanical waves on the surface of the sensor [8].

The diagnostic of knock sensor is based on the response of knock sensor on the first two extremes of the measured signal. The amplitude of the signal shows level of sensor sensitive and what is the shape of the sensor response. From the measured values we could specify a “normal curve” which shows how big the voltage response should be from this kind of sensor. It replaces the mounting used by the manufacturer for this sensor [9].

The value of the generated voltage depends on the gravitational potential energy of the falling bullet [10]:

$$E_v = m \cdot g \cdot h$$

where $m$ is the mass of the body (2050mg), $g$ is the acceleration due to gravity (9.81 m/s$^2$), and $h$ is the height of the body above the surface (5 cm, 10 cm, 15 cm, 20 cm, 25 cm, 30 cm, 40 cm, 50 cm).
Figure 9 shows the 3D model of the knock sensor. It is modelled on materials composition and functions like in real use. The cover of the sensor is made from plastic and electrodes are made from metal. Inner pressure sensitive layer is simulated by a crystal. On this model it is affecting outer force. The model is detailed because the response of the crystal is influenced by the sensor cover and the body of the sensor too. Figure 10 shows the knock sensor simulation in the COMSOL [12] at pressure of 1N. In Figure 10 we can see an electric potential of the sensor.

5. Conclusion

A construction of the testing device for the knock sensor suitable for diagnostics of the knock combustion in internal combustion engines has been presented.

The output signal of the presented sensor has been described by Bessel functions. Using the first voltage extremes on the characteristics from Figure 6 it is possible to create a reference for the evaluation of the polynomial residue. It should be taken into account that the velocity of sound in the air is 330 m/s. This sound impinges on the walls of the combustion chamber and is detected by the sensor. The resonant frequency of the clicking of the motor is usually in the range from 5 kHz to 15 kHz. The calculation of the output voltage can be realized by means of the formula:

\[ U = 20 \cdot \log(E_x + 1) \]  

(8)

Restriction reflecting the sound waves can be accomplished by changing the shape of a metallic material. An experiment was conducted where a steel ball was thrown directly at the sensor. In this impact we can already consider the Bessel function [11].
sensor worked in the field to 37 kHz, which shall be taken into account on an own sensor resonance.
